读取实时测试结果

S : FF 03 00 30 00 0D 91 DE

R : FF(从站地址) 03 (读取) 1A (字节数) 00 00 (程序号) 02 00 (寄存器中的结果数量) 01 00 (测试模式) 30 00 (仪器测试状态) FF FF (测试阶段) 00 00 00 00 (测试压力) F8 2A 00 00 (压力单位) 00 00 00 00 (泄漏量结果) 70 17 00 00 (泄漏量单位) 8C C8 (CRC)

最后测试结果读取：

S: FF 03 00 11 00 0C 00 14

R: FF 03 (读) 18 (字节) 00 00 (程序号) 02 00 (测试模式) 02 00 (测试状态 OK/NG/ALARM) 0C 00 (报警状态) 00 00 00 00 (压力值) 98 3A 00 00 (压力单位) 00 00 00 00 (泄漏量值) 70 17 00 00 (泄漏量单位) DE B7

注：在返回结果中所有用双字节或四字节表示的结果，在读取释意时需要高低位字节调换后再转换成十进制结果：

02 00 (HEX) = 00 02 (HEX) = 2 (d)
F8 2A 00 00 (HEX) = 00 00 2A F8 (HEX) = 11000 (d)

例：

1) 程序号：

00 00 (HEX) = 0 (Dec) = Program 1

01 00 (HEX) = 00 01 (HEX) = 1 (Dec) = Program 2

ATEQ 仪器程序号是从程序1开始，因此在读取到的原有十进制结果上加一才是当前的程序号。

2) 测试状态

01 00 (HEX) = 00 01 (HEX)

这里有两种方式可以判断仪器的测试状态（结束、OK、NG、ALARM 等）

方法一：将最终得到的十六进制结果转换为二进制结果，然后参照下表根据 BIT 位判断。

Status:

Bit 0 = 1: good part.

Bit 1 = 1: bad test part.

Bit 2 = 1: bad reference part.

Bit 3 = 1: alarm.

Bit 4 = 1: pressure error.

Bit 5 = 1: cycle end.

Bit 6 = 1: recoverable part.

Bit 7 = 1: CAL error or drift.

Bit 8 = 1: Calibration check error.

Bit 9 = 1: ATR error or drift.

Bit 10 = 1: unused.

Bit 11 = 1: unused.

Bit 12 = 1: unused.

Bit 13 = 1: unused.

Bit 14 = 1: unused.

Bit 15 = 1: key presence.

比如：01 00 (HEX) = 00 01 (HEX) = 1 (B) : good part

02 00 (HEX) = 00 02 (HEX) = 10 (B) : bad pat

04 00 (HEX) = 00 04 (HEX) = 100 (B) : alarm

21 00 (HEX) = 00 21 (HEX) = 100001 (B) : cycle end & good part

24 00 (HEX) = 00 24 (HEX) = 100100 (B) : cycle end & alarm

方法二：由于仪器状态只有几种状态，因此可以根据收到的十六进制中双字节的后一个字节来直接判断仪器的状态。

比如结果 00 01 后两位为 01: good part

00 02 后两位为 02: bad pat

00 21 后两位为 21: 2 表示 cycle end ; 1 表示 pass part

00 24 后两位为 24: 2 表示 cycle end ; 4 表示 alarm

因此状态位读取除了可以表示仪器的测试结果状态外，还可在实时测试中用于判断仪器是否已经启动，或处于 cycle end 状态。
